- Astrophysical backgrounds
- Summary
The Sagittarius dwarf spheroidal galaxy

- Discovered by Ibata, Gilmore, Irwin (1994)
- Heliocentric distance 24 kpc; on the opposite side of the Galactic Centre
- Brightest known Galactic dwarf spheroidal \( MV = -13.3 \)
- Shows clear evidence of ongoing tidal mass stripping in the form of an associated tidal stream => hard DM halo modelling
- Has been claimed to be among the best target for indirect DM searches, because of its near location
Indirect dark matter searches through gamma-rays

DM self-annihilation rate:

$$\Gamma \chi \approx \sigma v \frac{\rho^2}{m^2}$$

Gamma-ray flux from annihilation of a WIMP:

$$\frac{d\Phi(\Delta\Omega, E_\gamma)}{dE_\gamma} = \frac{1}{8\pi} \frac{\langle \sigma v \rangle}{m^2} \frac{dN_\gamma}{dE_\gamma} \times \overline{J}(\Delta\Omega) \Delta\Omega$$

where

Gamma spectrum: typically a continuum with an cut-off at the DM particle mass

and

$$\overline{J}(l, b) = \frac{1}{\Delta\Omega} \int_{\Delta\Omega} d\Omega \int_{\text{los}} \rho^2 [r(s)] ds$$

Opening angle of obs.: $$\Delta\Omega \approx 10^{-3} - 10^{-6} \text{sr}$$

Strong dependence on dark matter density distribution modeling; halo density profile model is needed
Indirect dark matter searches through gamma-rays

DM self-annihilation rate:

\[ \Gamma_\chi \approx \sigma v \frac{\rho_\chi^2}{m_\chi^2} \]

Gamma-ray flux from annihilation of a WIMP:

\[
\frac{d\Phi(\Delta\Omega, E_\gamma)}{dE_\gamma} = \frac{1}{8\pi} \left(\frac{\langle \sigma v \rangle}{m_\chi^2}\right) \frac{dN_\gamma}{dE_\gamma} \times \tilde{J}(\Delta\Omega) \Delta\Omega
\]

where

Gamma spectrum: typically a continuum with an cut-off at the DM particle mass

and

\[ \tilde{J}(l, b) = \frac{1}{\Delta\Omega} \int_{\Delta\Omega} d\Omega \int_{\text{los}} \rho^2[r(s)] ds \]

Opening angle of obs.: \[ \Delta\Omega \approx 10^{-3} - 10^{-6} \text{ sr} \]

Strong dependence on dark matter density distribution modeling; halo density profile model is needed
Indirect dark matter searches through gamma-rays

DM self-annihilation rate:

\[ \Gamma_\chi \approx \sigma v \frac{\rho_\chi^2}{m_\chi^2} \]

Gamma-ray flux from annihilation of a WIMP:

\[
\frac{d\Phi(\Delta\Omega, E_\gamma)}{dE_\gamma} = \frac{1}{8\pi} \frac{\langle \sigma v \rangle}{m_\chi^2} \frac{dN_\gamma}{dE_\gamma} \times \overline{J}(\Delta\Omega) \Delta\Omega
\]

where

Gamma spectrum: typically a continuum with an cut-off at the DM particle mass

and

\[
\overline{J}(l, b) = \frac{1}{\Delta\Omega} \int_{\Delta\Omega} d\Omega \int_{\text{los}} \rho^2[r(s)] \, ds
\]

Opening angle of obs.: \( \Delta\Omega \approx 10^{-3} \rightarrow 10^{-6} \text{ sr} \)

Strong dependence on dark matter density distribution modeling; halo density profile model is needed
$\rho(r) \rightarrow ?$

- Cosmological N-body numerical simulations $\Rightarrow$ Cusp profile
- Analytical solutions of the Jeans equation (hydrodynamics) $\Rightarrow$ Cored profile

Two different types of DM halo profiles are taken as examples:

- NFW profile: N-body simulations
- Cored profile: analytic resolution of the Jeans equation

The parameters are found after solving the Jeans equation from observation of the stars dynamics (luminous density, velocity dispersion, velocity anisotropy...) inside the galaxy.

**Problem:** The distribution of stars has been clearly altered from its original configuration by tidal mass stripping!
NFW profile

- Tightly bound dark matter cusp is more resilient to disruption
- The kinematics of stars that locate the central regions of the dwarf are not influenced by external tidal field

Jeans equations to search the DM halo parameters that best fit the observed stellar kinematics
Dark Matter halo modeling

**NFW profile**

- Tightly bound dark matter cusp is more resilient to disruption.
- The kinematics of stars that locate the central regions of the dwarf are not influenced by external tidal field.

Jeans equations to search the DM halo parameters that best fit the observed stellar kinematics.

**Isothermal cored profile**

*Peñarrubia, J. et al. (2010). MNRAS, 408, L26*

Leading and trailing tails show the future and past location of the progenitor system.

Streams trace orbits.

Orbits depend on DM halo potential.

Fit the known stream with semi-analytic orbits

Allows to recover the actual DM profile
In case of no gamma-ray signal, a limit on the number of gamma rays can be derived by:

- Numbers of gamma-ray in the signal region \(N_{ON}\) and background events \(N_{OFF}\) from measurements in a observation
- Assuming \(N_{ON} = N_{OFF}\) for a known background (model) in the sensitivities calculations

• The 95% C.L. limit on \(N_{\gamma}\) provides a 95% C.L. limit on the velocity-weighted cross section for a given DM profile:

\[
\langle \sigma v \rangle_{\text{min}}^{95\% \text{ C.L.}} = \frac{8\pi}{\mathcal{J}(\Delta \Omega) \Delta \Omega} \times \frac{m_X^2 N_{\gamma,\text{tot}}^{95\% \text{ C.L.}}}{T_{\text{obs}} \int_{0}^{m_X} A_{\text{eff}}(E_{\gamma}) \frac{dN_{\gamma}}{dE_{\gamma}}(E_{\gamma}) \, dE_{\gamma}}
\]

- the velocity-weighted cross-section is then calculated as function of the DM particle mass
- A spectrum of a typical Dark Matter particle annihilating into W and Z pairs is used (e.g. SUSY neutralino)
Using published H.E.S.S. data on Sagittarius dwarf:

- Updated limits with new halos models
- Old limits overestimate the DM gamma-ray flux
- Unrealistic DM halo models due to lack of accurate modelling of SgrDw at that time
- Projected upper limits and sensitivity for 50h
Next generation of IACTs: the CTA case

- About 100 telescopes of 3 different sizes: $\phi 23m$, $\phi 12m$, $\phi 6m$
- A factor 10 better in sensitivity than current instruments
- Wider energy range coverage, wider field of view, substantially better angular and energy resolution
Sensitivity curves to DM annihilation: CTA sensitivities

Using public CTA effective area:

- sensitivities are improved by more than one order of magnitude for DM masses above 1 TeV
- thermally-produced DM can be tested for specific wino masses in the resonance regions of the Sommerfeld effect
• Although are generally believed to contain very little background emission from conventional astrophysical sources, some gamma-ray emitting sources may still exist

• For instance, dwarf spheroidal galaxies can harbour globular clusters (M54 in the center of SgrDw), and globular cluster can host:

Milisecond pulsars population

• Collective emission of HE and VHE gamma-rays
• After 200h => 4σ - 60σ signal with reasonable assumption
• After 200h a thermally produced DM would give a 0.1σ signal

Abdo et al. 2010
Astrophysical background emission

- Although are generally believed to contain very little background emission from conventional astrophysical sources, some gamma-ray emitting sources may still exist.
- For instance, dwarf spheroidal galaxies can house globular clusters (M54 in the center of SgrDw), and globular cluster can host:
  
  ➢ Milisecond pulsars population
    - Collective emission of HE and VHE gamma-rays
    - After 200h ⇒ 4σ - 60σ signal with reasonable assumption
    - After 200h a thermally produced DM would give a 0.1σ signal

  ➢ Intermediate mass black hole
    - Gamma-ray emission of relativistic jets
    - Signal is not detectable
    - Jet inclination angle = 45° ⇒ conservative estimation
    - If jet is aligned with the line-of-sight it might be detectable

Astrophysical background emission

- Although are generally believed to contain very little background emission from conventional astrophysical sources, some gamma-ray emitting sources may still exist.

- For instance, dwarf spheroidal galaxies can harbour globular clusters (M54 in the center of SgrDw), and globular cluster can host:

  ➢ Milisecond pulsars population
    - Collective emission of HE and VHE gamma-rays
    - After 200h => 4σ - 60σ signal with reasonable assumption
    - After 200h a thermally produced DM would give a 0.1σ signal

  ➢ Intermediate mass black hole
    - Gamma-ray emission of relativistic jets
    - Signal is not detectable
    - Jet inclination angle = 45° => conservative estimation

The collective MSP signal would be a few orders of magnitude stronger than a thermally produced DM annihilation signal.
Summary and conclusions

- Older publications on DM searches towards SgrDw gave too optimistic constraints on particle dark matter self-annihilation cross sections => lack of accurate modelling of SgrDw at that time (still the case for several galaxies)

- Realistic models are now published => loosen the existing constraints by more than one order of magnitude

- The future CTA array will be sensitive to $<\sigma v>$ values around a few $10^{-25}$ cm$^3$ s$^{-1}$.

- Some models could be excluded after 200 hours of observation, if boosts factors are taken into account

- VHE emission of milisecond pulsars population could give an observable signal for long-enough observation times and be a challenging astrophysical gamma ray background to overcome

- The candidate IMBH located at the center is not expected to give an observable signal => Under favorable circumstances (active black hole and jet aligned towards the line of sight), it might nevertheless be detectable in observations of SgrDw.

Dark Matter halo modeling

• From Jeans Equation: \[ M(r) = r \left( \langle v_r^2 \rangle \right) \left( \frac{d \ln \rho}{d \ln r} + \frac{d \ln \langle v_r^2 \rangle}{d \ln r} - 2\beta \right) \]

- \( \langle v_r^2 \rangle \): radial velocity dispersion
- \( \rho \): luminous density
- \( M \): luminous + dark mass
- \( \beta \): anisotropy

- solve for \( M(r) \) to get \( \rho_{\text{dark}} \)

- Assumed \( \beta(r) \)

OR

- fit DM halo parameters to \( \langle v_r^2 \rangle \)

• Two different types of DM halo profiles are produced:

- **NFW profile**: fit of \((\rho_s, r_s)\) parameters to \( \langle v_r^2 \rangle \)

- **cored profile**: evolution code of the stellar profile \( \Rightarrow \) analytic resolution of the Jeans equation

\[
\rho_{\text{NFW}}(r) = \frac{\rho_s}{(r / r_s)(1 + r / r_s)^2}
\]

\[
\rho_{\text{ISO}}(r) = \frac{m_h \alpha}{2\pi^{3/2} r_{\text{cut}}} \exp\left[-\left(\frac{r / r_{\text{cut}}}{r_c}ight)^2\right]
\]

\( m_h \alpha \): unknown
Dark Matter halo modeling

- Two different types of DM halo profiles are produced:
  - NFW profile: fit of \((\rho_s, r_s)\) parameters to \(<v_r^2>\)
  - cored profile: evolution code of the stellar profile \(\Rightarrow\) analytic resolution of the Jeans equation

\[
\rho_{NFW}(r) = \frac{\rho_s}{(r / r_s)(1 + r / r_s)^2} \\
\rho_{ISO}(r) = \frac{m_h \alpha}{2\pi^{3/2} r_{cut}} \exp\left[-(r / r_{cut})^2\right] \left(\frac{r_c^2}{r_c^2 + r^2}\right)
\]

Table 1: Values of the LOS-integrated squared density averaged over the solid angle \((\bar{J})\) expressed in units of \(10^{23}\) GeV\(^2\) cm\(^{-5}\), for different solid angles \(\Delta\Omega\). The values of \(\bar{J}\) are calculated for the NFW and ISO DM halo profiles. The parameters of these profiles are given in the first column.
